Surface emission of neutron stars

NS Radii

A NS with homogeneous surface temperature and local blackbody emission

NS Radii - II

Real life is a trifle more complicated... Atmospheres.

Because of the strong B field Photon propagation different Surface temperature is not homogeneous Local emission may be not exactly planckian

Gravity effects are important

Uncertainties in temperature

- Atmospheres (composition)
 Magnetic field
- Non-thermal contributions to the spectrum
- Distance
- Interstellar absorption
- Temperature
 distribution

(Pons et al. astro-ph/0107404)

Non-uniform temperature distribution

In the case of RX J1856 because of significant (~6) optical excess it was proposed that there is a spot, or there is a continuous temperature gradient.

Trumper astro-ph/0502457

NS Thermal Maps

Electrons move much more easily along B than across B z' Greenstein & Hartke (1983) Therma ppic hv_B or inside a Surface Temperature ρ >> 10 Envelop B ~ con \square То

 $T_{S} = \left[\cos^{2}\Theta + \left(K_{perp} / K_{par}\right)\sin^{2}\Theta\right]^{1/4}T_{pole}$ $K_{perp} / K_{par} << 1$ K - conductivity $T_{s} = \left|\cos\Theta\right|^{1/2} T_{pole}$ Valid for strong fields: $K_{perp} \ll K_{par}$

Core centered dipole

Core centered quadrupole

Zane, Turolla astro-ph/0510693

Local Surface Emission

Much like normal stars NSs are covered by an atmosphere Because of enormous surface gravity, $g \approx 10^{14} \text{ cm/s}^2$, $h_{atm} \approx 1-10 \text{ cm} (h_{atm} \sim kT/mg)$ Spectra depend on g, chemical composition and magnetic field Plane-parallel approximation (locally)

Atmospheric composition

As *h*<<*R* we can consider only flat layers.

Due to strong gravity an atmosphere is expected to be separated: lighter elements on top.

Because of that even a small amount of light elements (hydrogen) results in its dominance in the properties of the atmosphere.

10⁻²⁰ solar mass of hydrogen is enough to form a hydrogen atmosphere.

Free-free absorption dominates

 $\kappa_{\nu} \propto \nu^{-3}, h\nu \gg kT$

 High energy photons decouple deeper in the atmosphere where T is higher

Rapid decrease of the light-element opacities with energy $(\sim E^{-3})$

^a 3 σ ranges, assuming z = 0.305. Weighting of the data is discussed in the text.

^b Uncertainty does not include uncertainty in distance.

° The likelihood that the X-ray and optical parameters are the same.

Fits of realistic spectra of cooling NSs give higher temperature (and so smaller emitting surfaces) for blackbody and heavy element atmospheres (Fe, Si). T_{BB}~2T_H

Different fits

Pons et al. 2002

Cas A carbon atmosphere

Low-field carbon atmosphere can fit the data. Before all fits provided a very small emitting area.

STEP 1

Specify viewing geometry and B-field topology; compute the surface temperature distribution

STEP 2

Compute emission from every surface patch

STEP 3

GR ray-tracing to obtain the spectrum at infinity

STEP 4

Predict lightcurve and phase-resolved spectrum Compare with observations

The Seven X-ray dim Isolated NSs

- Soft thermal spectrum (kT \approx 50-100 eV)
- No hard, non-thermal tail
- Radio-quiet, no association with SNRs
- Low column density ($N_H \approx 10^{20} \text{ cm}^{-2}$)
- **X**-ray pulsations in all (but one?) sources ($P \approx 3-10$ s)
- Very faint optical counterparts
- Broad spectral features

ICoNS: The Perfect Neutron Stars

ICoNS are key in neutron star astrophysics: these are the only sources for which we have a "clean view" of the star surface

- Information on the thermal and magnetic surface distributions
- Estimate of the star radius (and mass ?)
- Direct constraints on the EOS

ICoNS: What Are They ?

- ICoNS are neutron stars
- Idea number 1: Powered by ISM accretion?
 M
 M
 Bondi ~ n_{ISM}/v³ if v < 40 km/s and D < 500 pc (e.g. Treves et al 2000)
- Measured proper motions imply v > 100 km/s
 Just cooling NSs

Simple Thermal Emitters ?

Recent detailed observations of ICoNS allow direct testing of surface emission models

"STANDARD MODEL" thermal emission from the surface of a neutron star with a dipolar magnetic field and covered by an atmosphere

The optical excess ICoNS lightcurves The puzzle of RX J1856.5-3754 Spectral evolution of RX J0720.4-3125

BB+line

Non-uniform distrubution

Pulsating ICoNS - I

Quite large pulsed fractions

- Skewed lightcurves
- Harder spectrum at pulse minimum
- Phase-dependent absorption features

Pulsating ICoNS - II

Core-centred dipole field

Atmosphere =

Too small pulsed fractions Symmetrical pulse profiles (Zane & Turolla 2006)

Crustal Magnetic Fields

- Star centred dipole + poloidal/toroidal field in the envelope (Geppert, Küker & Page 2005; 2006)
- Purely poloidal crustal fields produce a steeper meridional temperature gradient
- Addition of a toroidal component introduces a N-S asymmetry

Indications for non-antipodal Caps (Schwope et al 2005)

Need for a non-axisymmetric treatment of heat transport

RX J1856.5-3754 - I

Blackbody featureless spectrum in the 0.1-2 keV band (Chandra 500 ks DDT, Drake et al 2002); possible broadband deviations in the XMM 60 ks observation (Burwitz et al 2003)

RX J1856 multiwavelength SED (Braje & Romani 2002)

Thermal emission from NSs is not expected to be a featureless BB ! H, He spectra are featureless but only blackbody-like (harder). Heavy elements spectra are closer to BB but with a variety of features

RX J1856.5-3754 - II

What spectrum ? The optical excess ?

A quark star (Drake et al 2002; Xu 2002; 2003)
 A NS with hotter caps and cooler equatorial region (Pons et al 2002; Braje & Romani 2002; Trümper et al 2005)

A bare NS (Burwitz et al 2003; Turolla, Zane & Drake 2004; Van Adelsberg et al 2005; Perez-Azorin, Miralles & Pons 2005)

A perfect BB ?

The Optical Excess

In the most of the sources with a confirmed optical counterpart $F_{opt} \approx 5-10 \times B_{v}(T_{BB.X})$ • $F_{opt} \approx v^2$? **Deviations from a Rayleigh-**Jeans continuum in RX J0720 (Kaplan et al 2003) and RX J1605 (Motch et al 2005). A non-thermal power law?

RX J1605 multiwavelength SED (Motch et al 2005)

Bare Neutron Stars

At $B >> B_0 \sim 2.35 \times 10^9$ G atoms

Spectra from Bare NSs - I

The cold electron gas approximation. Reduced emissivity expected below ω_p (Lenzen & Trümper 1978; Brinkmann 1980)

Spectra are very close to BB in shape in the 0.1 - 2 keV range, but depressed wrt the BB at T_{eff} . Reduction factor ~ 2 - 3.

Turolla, Zane & Drake (2004)

Spectra from Bare NS - II

Proper account for damping of free electrons by lattice interactions (e-phonon scattering; Yakovlev & Urpin 1980; Potekhin1999)

Spectra deviate more from BB. Fit in the 0.1 – 2 keV still acceptable. Features may be present. Reduction factors higher.

Turolla, Zane & Drake (2004)

Is RX J1856.5-3754 Bare ?

- Fit of X-ray data in the 0.15-2 keV band acceptable
- Radiation radius problem eased
- Optical excess may be produced by reprocessing of surface radiation in a very rarefied atmosphere (Motch, Zavlin & Haberl 2003; Zane, Turolla & Drake 2004; Ho et al. 2006)
- Details of spectral shape (features, low-energy behaviour) still uncertain

$$R_{\infty} = 4.25 f_E^{-1/2} \left(\frac{D}{100 \text{ pc}} \right) \left(\frac{T_{BB}}{60 \text{ keV}} \right)^{-2} \text{ km}$$

Does the atmosphere keep the star surface temperature ?

What is the ion ^{10⁻¹} What is the ion contribution to the dielectric tensor ? (Van Adelsberg et al. 2005; Perez-Azorin, Miralles & Pons 2005)

Condensed iron surface emissivity

Free ions approximation.

Thin hydrogen magnetized atmosphere above blackbody and iron condensed surface

Below atmosphere was a blackbody spectrum

Below – iron condensed surface

1006.3292

Let us make it realistic

Excess at >1 keV?

Analysis of spectra of M7 demonstrated a strange excess at energies > 1 keV. This is somehow similar to what magnetars demonstrate.

Light curves and pulsed fraction

Polarization

Contour plots for the phase-averaged polarization fraction at optical (2 eV, left panel) and X-ray (0.3 keV, right panel)

For RX J1856 polarization was detected in optics: 1610.08323.

1509.05023, see 2001.07663 about polarization in magnetars

Low-field magnetar SGR 0418+5729

Fitting parameters of the magnetized atmosphere it is possible to show, that the low-field solution is not acceptable. This can be due to non-dipolar field components.

New results in 1507.02689

Conclusions

- Emission from cooling NSs is more complicated than a simple blackbody
- Light bending (gravity)
- Atmospheres
- Magnetic field distribution effects on properties of atmospheres and emission
- Magnetic field (including toroidal) in the crust non-uniform temp.distr.
- Condensate
- Rotation at ~msec periods can smear spectral lines
