$$K=1.2293 \cdot 10^{15} \text{ (CGS)}$$

# Neutron stars

## Superdense matter and superstrong magnetic fields

# Proto-neutron stars

Mass fraction of nuclei in the nuclear chart for matter at  $T = 1 \text{ MeV}$ ,  $n_B = 10^{-3} \text{ fm}^{-3}$ , and  $Y_p = 0.4$  (proton fraction). Different colors indicate mass fraction in  $\text{Log}_{10}$  scale.

1202.5791

NS EoS are also important for SN explosion calculation, see 1207.2184

# EoS for core-collapse, proto-NS and NS-NS mergers

	Core-collapse supernovae	Proto-neutron stars	Mergers of compact binary stars
$n/n_s$	$10^{-8} - 10$	$10^{-8} - 10$	$10^{-8} - 10$
$T(\text{MeV})$	0 - 30	0 - 50	0 - 100
$Y_e$	0.35 - 0.45	0.01 - 0.3	0.01 - 0.6
$S(k_B)$	0.5 - 10	0 - 10	0 - 100

Wide ranges of parameters

---

# Astrophysical point of view

**Astrophysical appearance of NSs  
is mainly determined by:**

- **Spin**
- **Magnetic field**
- **Temperature**
- **Velocity**
- **Environment**

The first four are related to the NS structure!

---

# Equator and radius

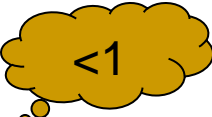

$$ds^2 = c^2 dt^2 e^{2\Phi} - e^{2\lambda} dr^2 - r^2 [d\theta^2 + \sin^2\theta d\varphi^2]$$

In flat space  $\Phi(r)$  and  $\lambda(r)$  are equal to zero.

•  $t = \text{const}, r = \text{const}, \theta = \pi/2, 0 < \varphi < 2\pi$   $\implies l = 2\pi r$

•  $t = \text{const}, \theta = \text{const}, \varphi = \text{const}, 0 < r < r_0$   $\implies dl = e^\lambda dr \implies l = \int_0^{r_0} e^\lambda dr \neq r_0$

# Gravitational redshift

$$d\tau = dt e^{\Phi},$$

$$\nu_r = \frac{dN}{d\tau} = e^{-\Phi} \frac{dN}{dt} \longrightarrow \text{Frequency emitted at } r$$

$$r \rightarrow \infty \quad \Phi \rightarrow 0 \quad \nu_\infty = \frac{dN}{dt} \longrightarrow \text{Frequency detected by an observer at infinity}$$

$$\nu_\infty = \nu_r e^{\Phi} \Rightarrow \Phi(r) \longrightarrow \text{This function determines gravitational redshift}$$

$$e^{2\lambda} \equiv \frac{1}{1 - \frac{2Gm}{c^2 r}}$$

It is useful to use  $m(r)$  – gravitational mass inside  $r$  – instead of  $\lambda(r)$

# Outside of the star

$$r > R \Rightarrow m(r) = M = \text{const}$$

$$e^{2\Phi} = 1 - \frac{2GM}{c^2 r} = 1 - \frac{r_g}{r}, \quad r_g = \frac{2GM}{c^2}$$

$$ds^2 = \left(1 - \frac{r_g}{r}\right) c^2 dt^2 - \left(1 - \frac{r_g}{r}\right)^{-1} dr^2 - r^2 d\Omega^2$$

$$v_\infty = v_r \sqrt{1 - \frac{r_g}{r}}$$

redshift

Bounding energy  $\longrightarrow \Delta M = M_b - M \sim 0.2 M_{\text{sun}}$

Apparent radius  $\longrightarrow R_\infty = R / \sqrt{1 - r_g / R}$

# Bounding energy

If you drop a kilo on a NS, then you increase its mass for  $<$  kilo

$M_{\text{acc}}$  is shown with color

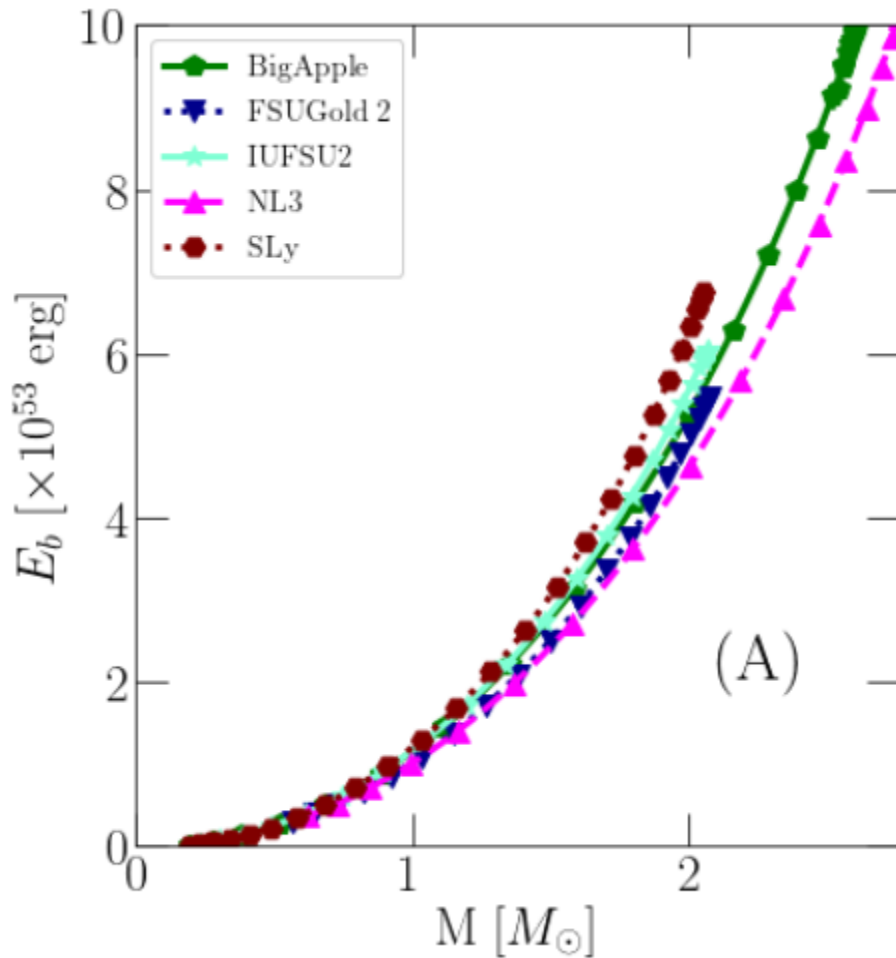

$M_{G,i}$ ( $M_{\odot}$ )	$\Delta M_G$ ( $M_{\odot}$ )	$M_{B,i}$ ( $M_{\odot}$ )		$M_{\text{acc}} (\Delta M_B)$ ( $M_{\odot}$ )

IU-FSU <sub>max</sub>	0.05	35	358	374	586
	0.10	232	555	854	1066

The maximum initial rotational frequency of a neutron star whose crust will never fail from slowing down, assuming a breaking strain of  $\sigma = 0.1$ .

Failure of the crust can be the reason of the limiting frequency. Spinning-up of a NS due to accretion can result in crust failure. Then the shape of the star is deformed, it gains ellipticity. So, GWs are emitted which slow down the compact object.

# EoS

(Weber et al. ArXiv: 0705.2708 )

# Mass-radius

Mass and radius are macroscopical potentially measured parameters.

Thus, it is important to formulate EoS in terms of these two parameters.

About hyperon stars see a review in 1002.1658.

About strange stars and some other exotic options – 1002.1793

Mass-radius relations for CSs with possible phase transition to deconfined quark matter.

# Mass-radius relation

## Main features

- Max. mass
- Diff. branches (quark and normal)
- Stiff and soft EoS
- Small differences for realistic parameters
- Softening of an EoS with growing mass

Rotation is neglected here.

Obviously, rotation results in:

- larger max. mass
- larger equatorial radius

Spin-down can result in phase transition, as well as spin-up (due to accreted mass), see 1109.1179

Haensel, Zdunik  
astro-ph/0610549

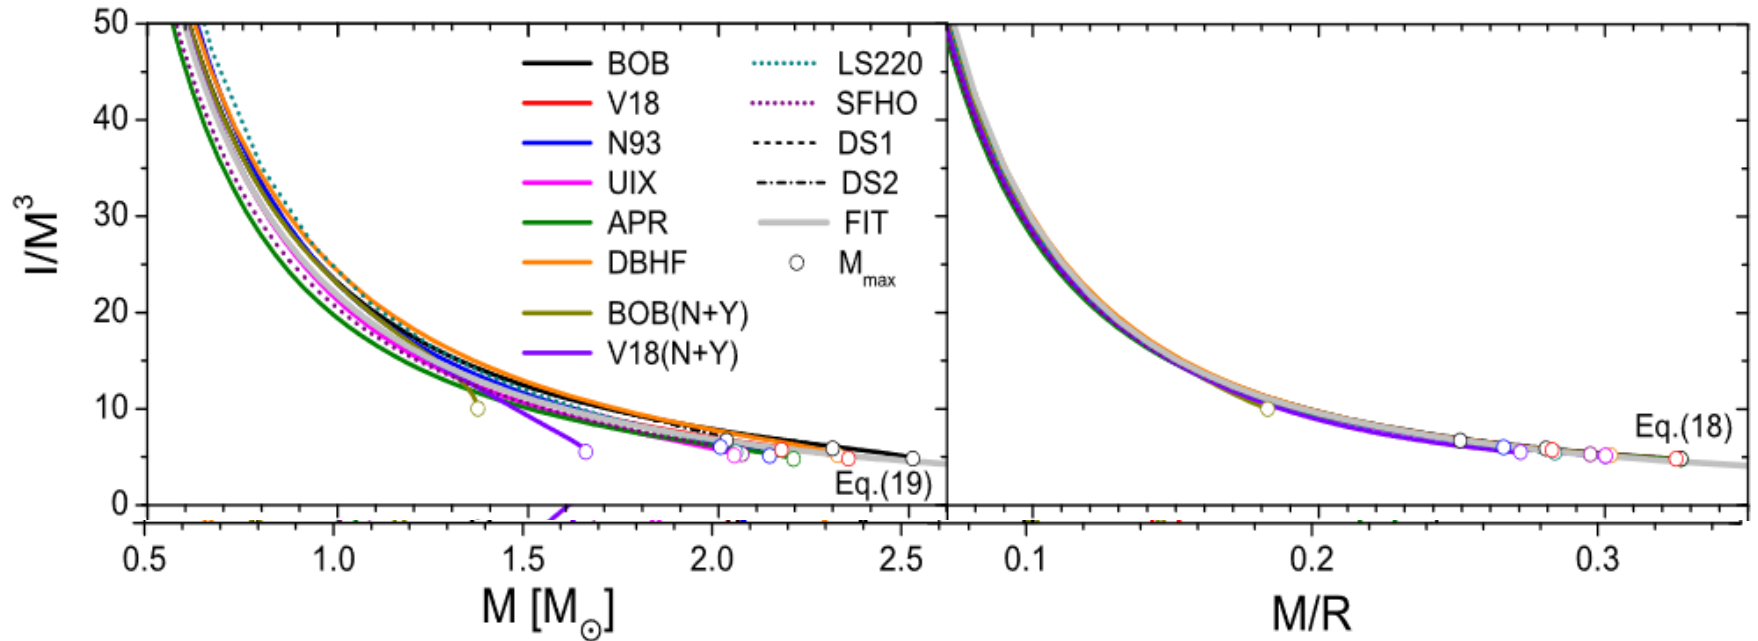

# Fitting formulae for moment of inertia

$$\frac{I}{M^3} \equiv 0.8134 \beta^{-1} + 0.2101 \beta^{-2} + 0.003175 \beta^{-3} - 0.0002717 \beta^{-4} \quad (18)$$

$$\frac{I}{M^3} \equiv 1.0334 M^{-1} + 30.7271 M^{-2} - 12.8839 M^{-3} + 2.8841 M^{-4} \quad (19)$$

$$\beta = Gm/(Rc^2)$$

# Fits for $I/MR^2$

$$\frac{I}{MR^2} \approx 0.189 + 0.118 \frac{M}{M_{\odot}} \pm 0.016.$$

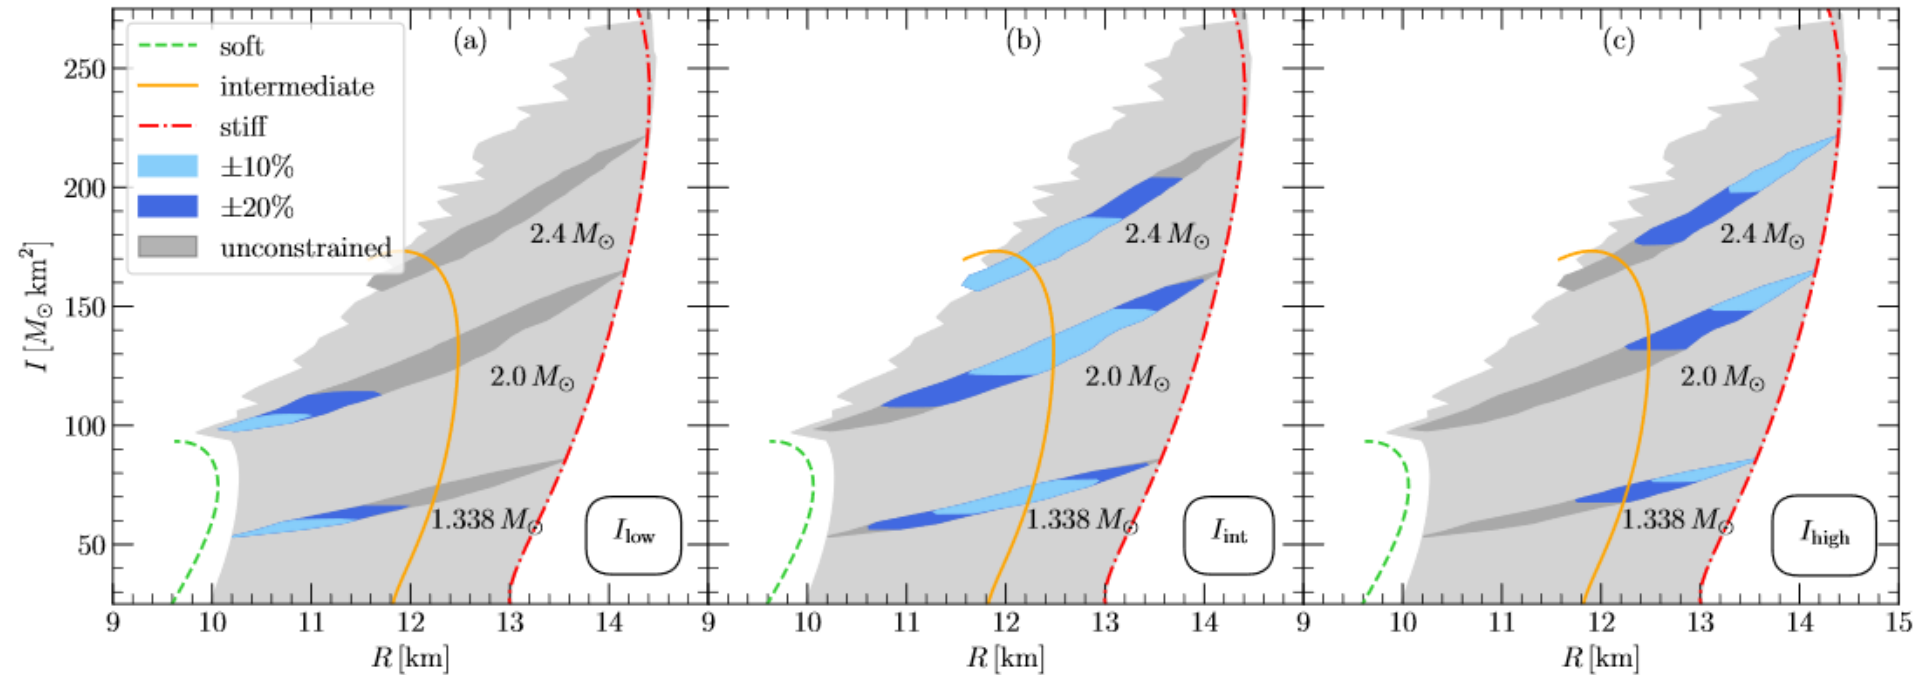

$$\frac{I}{MR^2} \approx (0.237 \pm 0.008)(1 + 2.844\beta + 18.91\beta^4)$$

$$\frac{I}{MR^2} \equiv 0.207 + 0.857\beta \pm 0.011$$

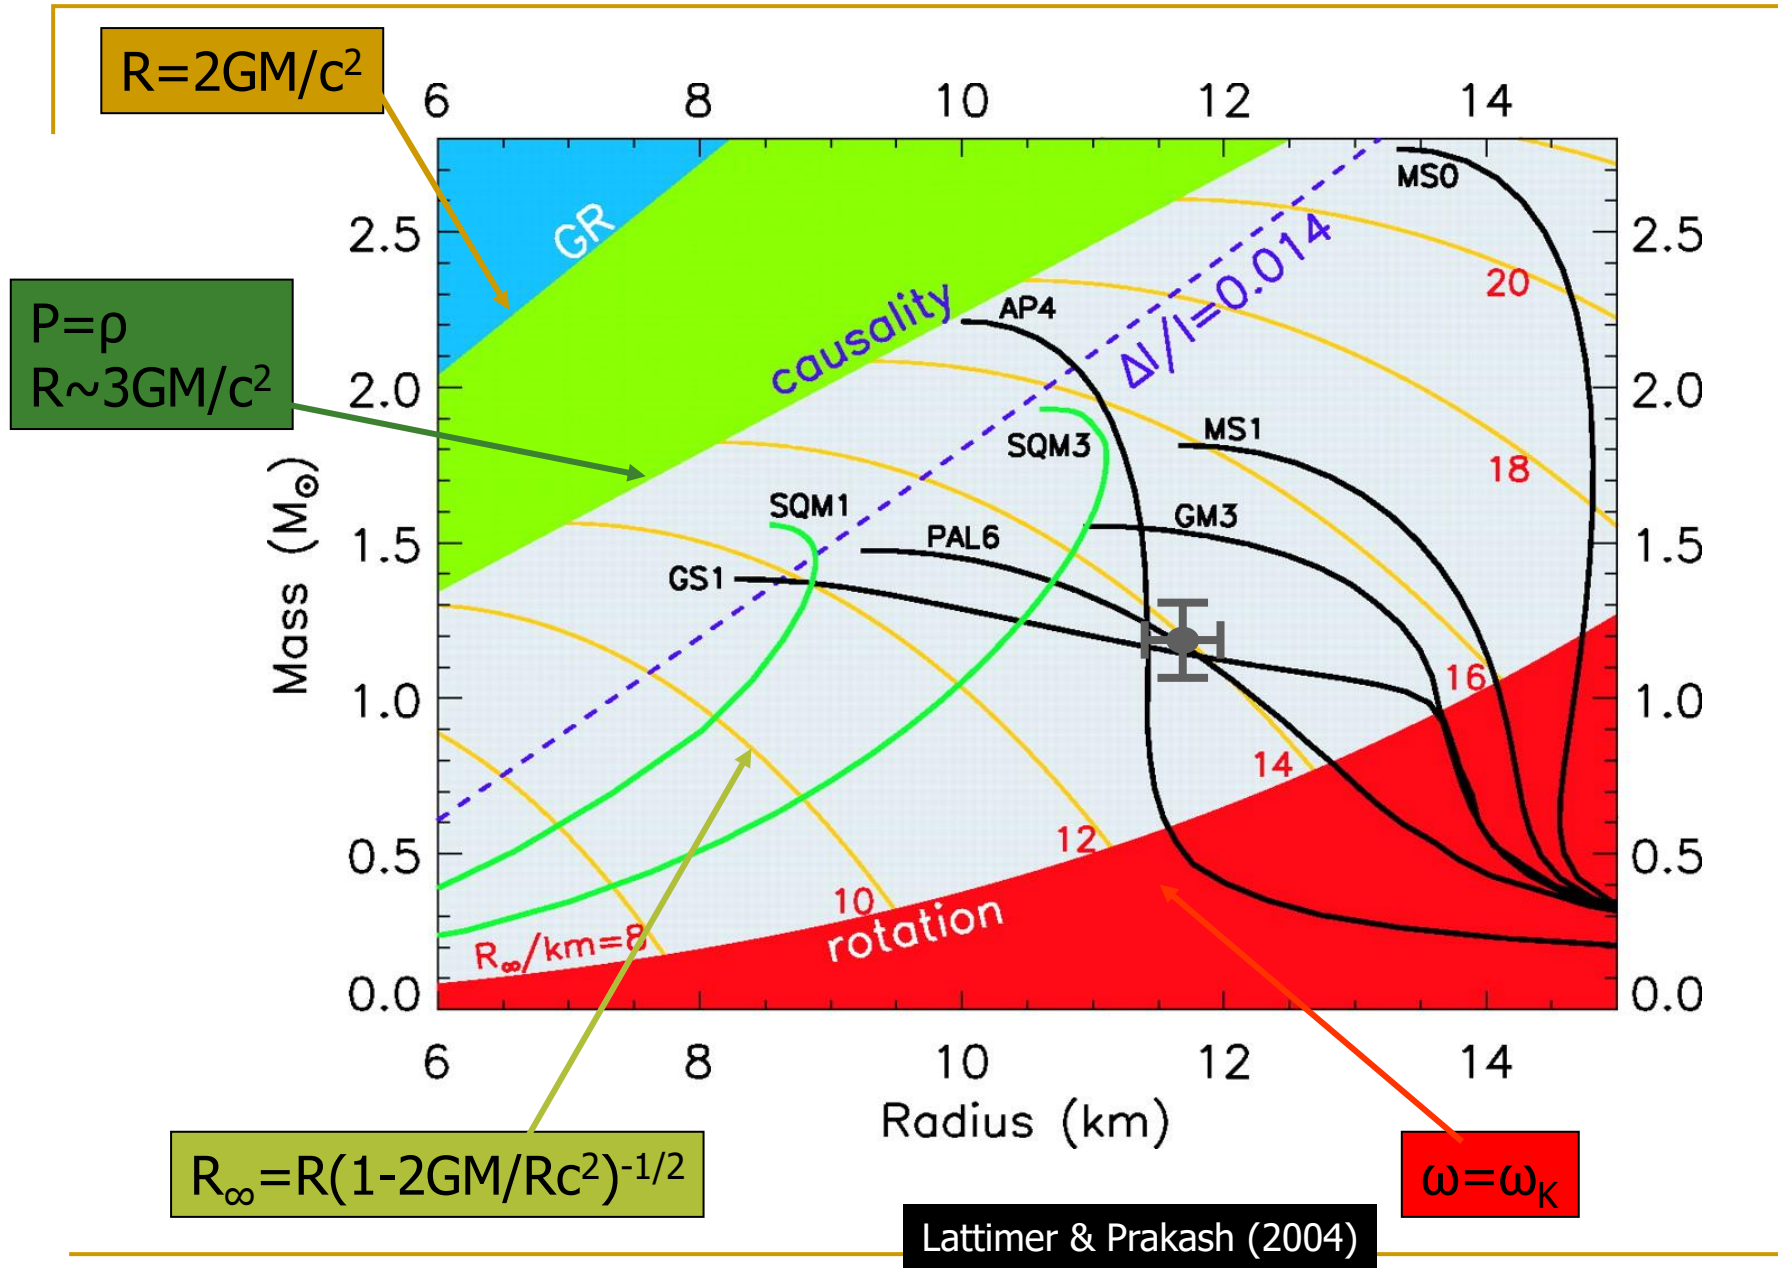

# Moment of inertia measurements to constrain EoS

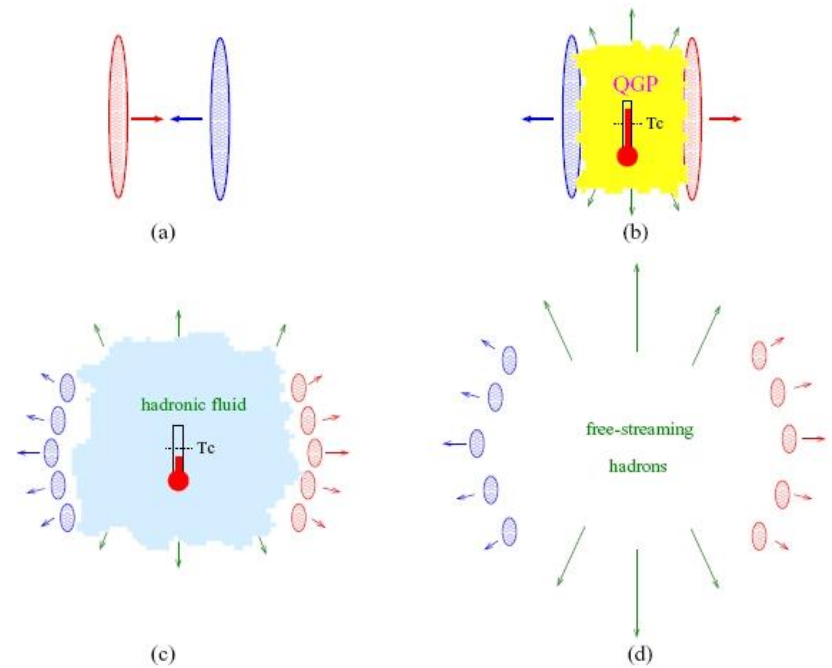

Precise ( $\pm 10\%$ ) measurements of a moment of inertia can significantly constrain the range of allowed radii for a given EoS.

# Theory vs. observations

# Au-Au collisions

# Experimental results and comparison

$$1 \text{ MeV/fm}^3 = 1.6 \cdot 10^{32} \text{ Pa}$$

(d)  $t = 4.0$  ms

Turbulent deflagration,  
as in SNIa.

Neutrino signal due to  
conversion of a NS into  
a quark star was calculated  
in 1304.6884

# Hybrid stars

Stars with quark cores are reviewed in 1904.05471

See also [1302.4732](#), [1903.08963](#), [1903.09121](#)

# Massive hybrid stars

Stars with quark cores can be massive, and so this hypothesis is compatible with existence of pulsars with  $M > 2 M_{\text{solar}}$

# Pion stars

New exotic solution.

It is not clear if it can be applied to any known type of sources.

# NS interiors: resume

(Weber et al. ArXiv: 0705.2708)

# Maximum mass

Maximum mass of NSs depends on the EoS, however, it is possible to make calculations on the base of some fundamental assumptions.

astro-ph/9608059

Seminal paper: Rhoades, Ruffini 1974

[http://prl.aps.org/abstract/PRL/v32/i6/p324\\_1](http://prl.aps.org/abstract/PRL/v32/i6/p324_1)

$$c_s^2 = \frac{dP}{d\rho} = c^2.$$

# NS-NS coalescence and EoS

GW signals for different EoS for two non-spinning 1.4 solar mass NSs. Vertical dashed line correspond to 1kHz frequency. Differences are due to different tidal response.

# Constraints on the M-R plane

# Calculations based on recent data on NS-NS coalescence

What uniform rotation can give:  $M_{\max} = (1.20^{+0.02}_{-0.02}) M_{\text{TOV}}$  independently of the EOS

# Another constraint from GW170817

$$M_{\text{NSNS}} \approx 2.74 \lesssim M_{\text{thresh}} \approx \alpha M_{\text{max}}^{\text{sph}}. \quad \leftarrow \text{As there was no prompt collapse}$$

Here  $\alpha \approx 1.3 - 1.7$  is the ratio of the HMNS threshold mass limit to the NS spherical maximum mass as gleaned from multiple numerical experiments of merging NSNSs

$$M_{\text{NSNS}} \approx 2.74 \gtrsim M_{\text{max}}^{\text{sup}} \approx \beta M_{\text{max}}^{\text{sph}},$$

where  $\beta \approx 1.2$  is the ratio of the uniformly rotating supra-massive NS limit to the nonrotating spherical maximum

$$M_{\text{max}}^{\text{sph}} = 4.8 \left( \frac{2 \times 10^{14} \text{ gr/cm}^3}{\rho_m/c^2} \right)^{1/2} M_{\odot}, \quad \text{- TOV limit from causality}$$

$$M_{\text{max}}^{\text{sup}} = 6.1 \left( \frac{2 \times 10^{14} \text{ gr/cm}^3}{\rho_m/c^2} \right)^{1/2} M_{\odot},$$

$$\beta \approx 1.27.$$

$$2.74/\alpha \lesssim M_{\text{max}}^{\text{sph}} \lesssim 2.74/\beta$$

$$M_{\text{max}}^{\text{sph}} \lesssim 2.16. \quad \beta \approx 1.27.$$

$$M_{\text{max}}^{\text{sph}} \lesssim 2.28. \quad \beta = 1.2$$
