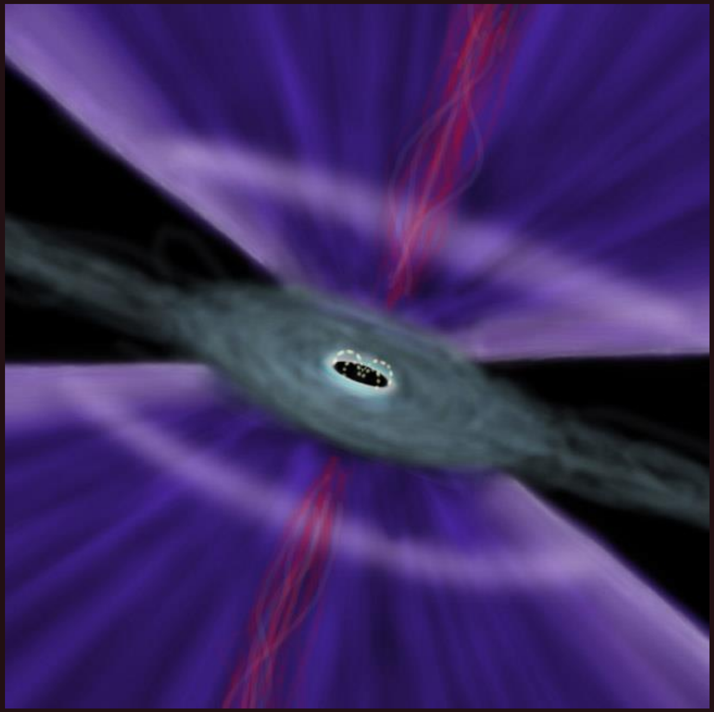
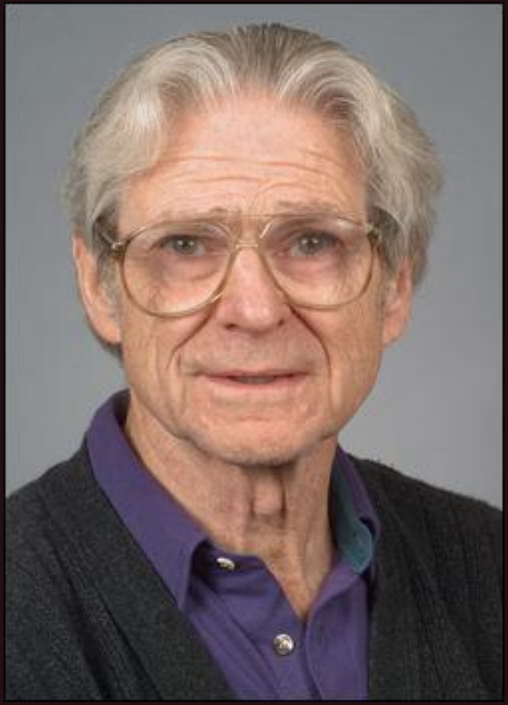
Some history

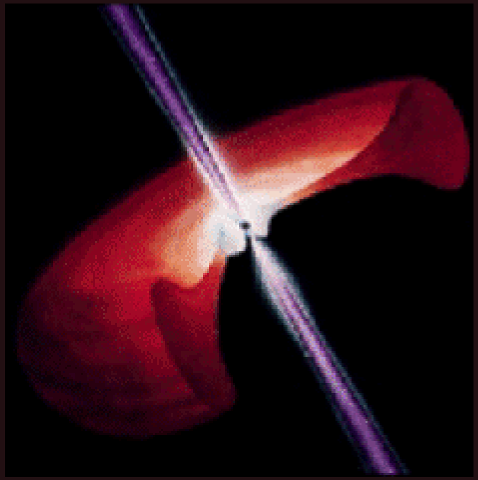
The story starts in 60-s when the first quasars have been identified (Schmidt 1963). Immediately the hypothesis about accretion onto supermassive BHs was formulated (Salpeter, Zeldovich, Novikov, Linden-Bell).



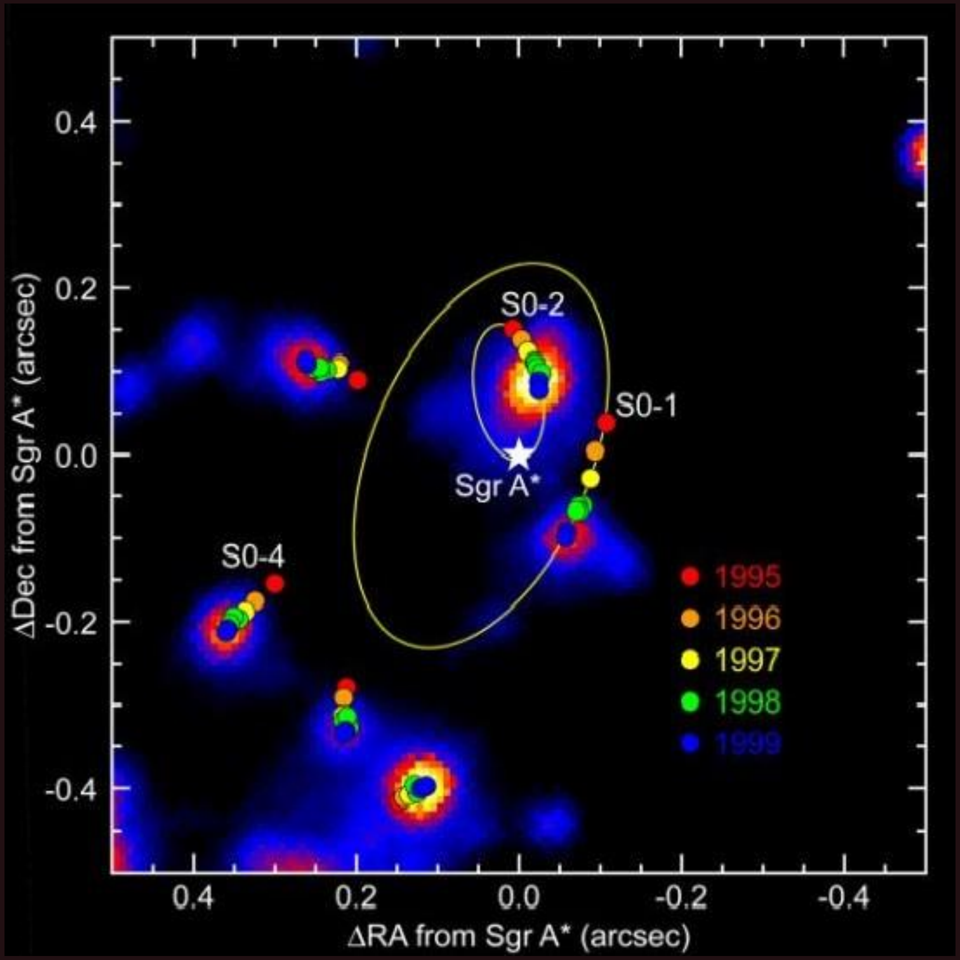


General info

- All galaxies with significant bulges should have a SMBH in the center.
- SMBH are observed already at redshifts z ~ 7 and even further
- Several percent of galaxies have active nuclei
- Now we know tens of thousand of quasars and AGNs, all of them can be considered as objects with SMBHs
- Measured masses of SMBHs are in the range $10^6 – 10^{10}$ solar masses.
- Masses are well-measured for tens of objects.
- The most clear case of a SMBH is Sgr A*.



Sgr A*



The case of Sgr A* is unique. Thanks to direct measurements of several stellar orbits it is possible to get a very precise value for the mass of the central object.

Also, there are very strict limits on the size of the central object. This is very important taking into account alternatives to a BH.

The star SO-2 has the orbital period 15.2 yrs and the semimajor axis about 0.005 pc.

A review: arXiv: 1501.02171 **The Galactic Center Black Hole Laboratory**

The region around Sgr A*

(Park et al.; Chandra data)
astro-ph/0311460

The result of summation of 11 expositions by Chandra (590 ksec).

Red 1.5-4.5 keV,
Green 4.5-6 keV,
Blue 6-8 keV.

The field is 17 to 17 arcminutes (approximatelly 40 to 40 pc).

Multiwavelength observations of Sgr A* are summarized in 1501.02164.

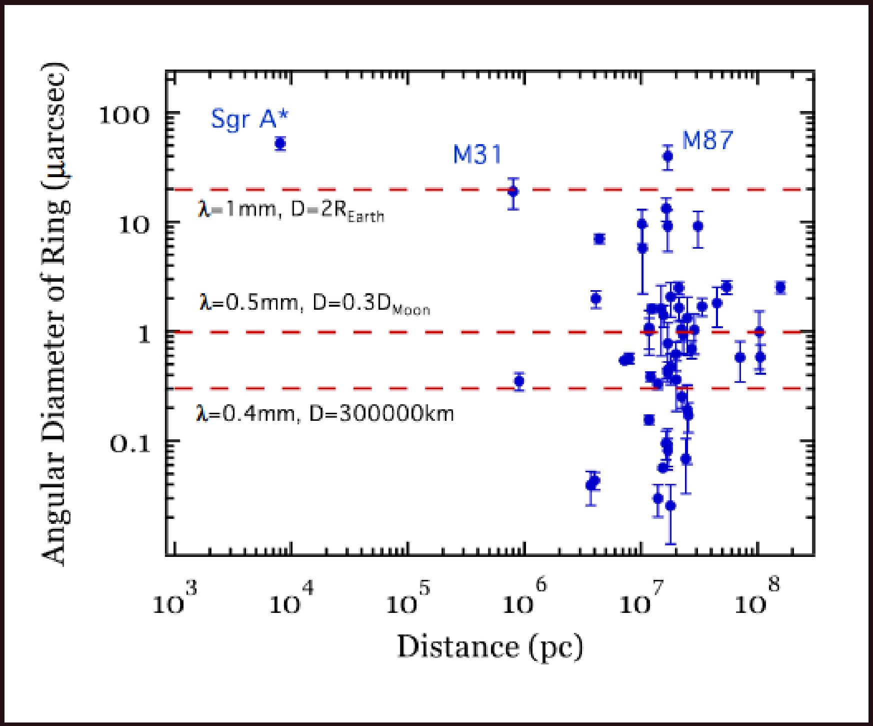
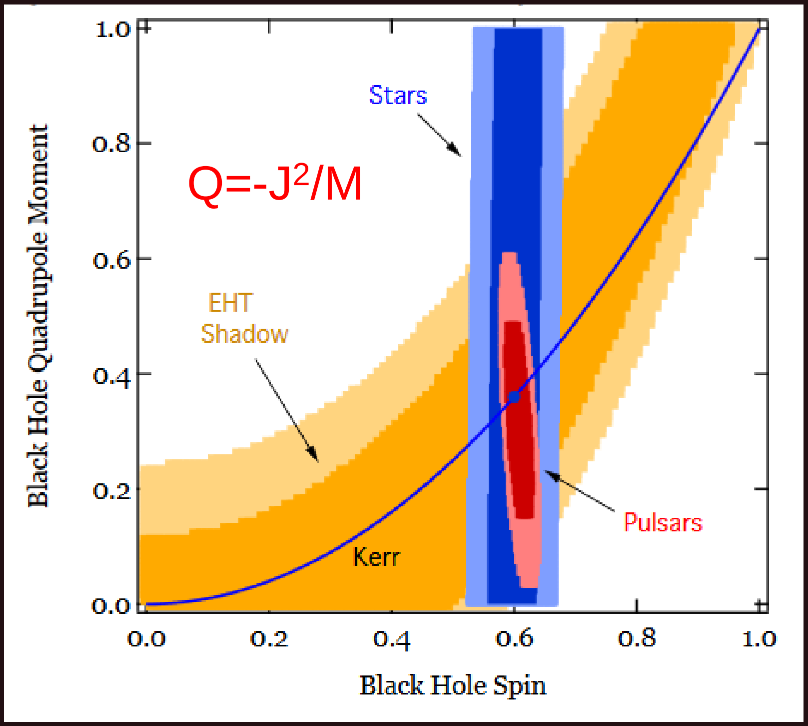
1512.03818



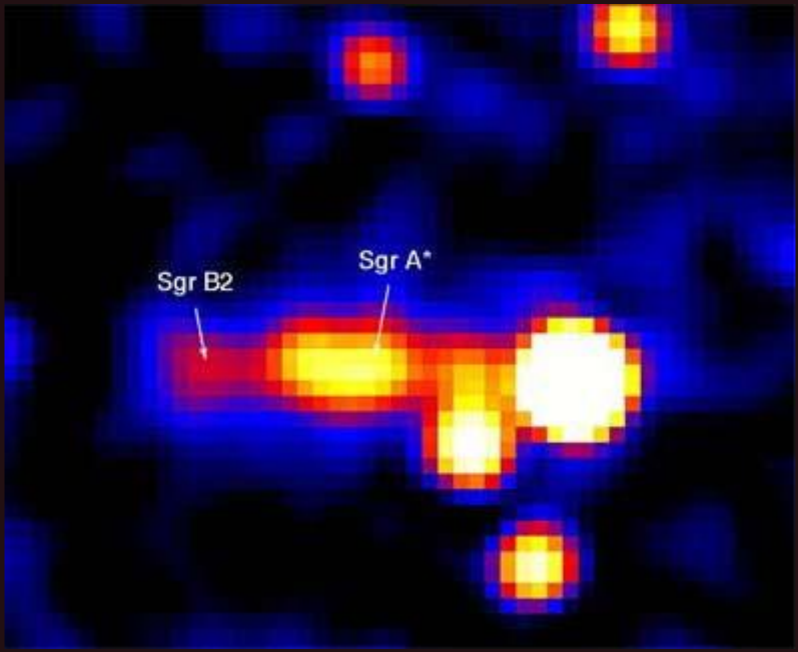


1510.00394

In the very near future Sgr A* might be the best laboratory to study GR. EHT observations and identifications of PSRs in the vicinity of the BH might help to probe the no-hair theorem and determine the main properties of the BH with high precision.

About EHT see 1410.2899

Observations aboard Integral



(Revnivtsev et al.)

The galactic center region is regularly monitored by Integral.

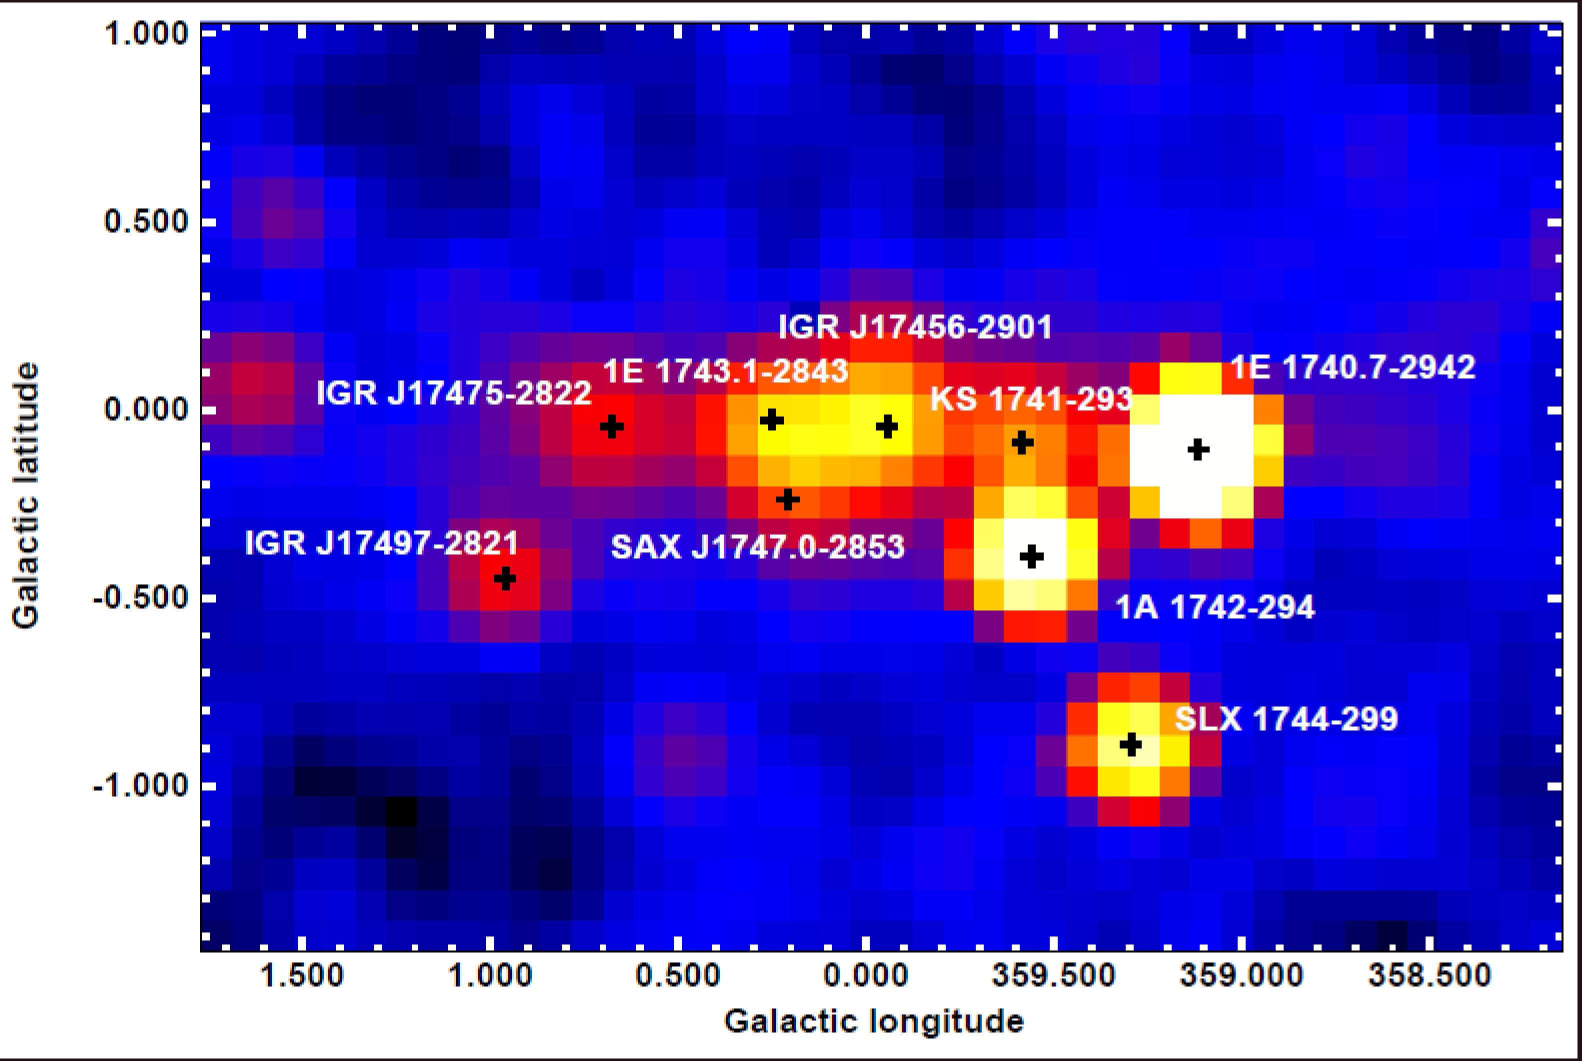
At present “our” black hole is not active. However, it was not so in the past.

It is suspected that about 350 years ago Sgr A* was in a “high state”.
Now the hard emission generated by Sgr A* at this time reached Sgr B2.
Sgr B2 is visible due to fluorescence of iron.

See more data in 1211.4529, 1612.00180.

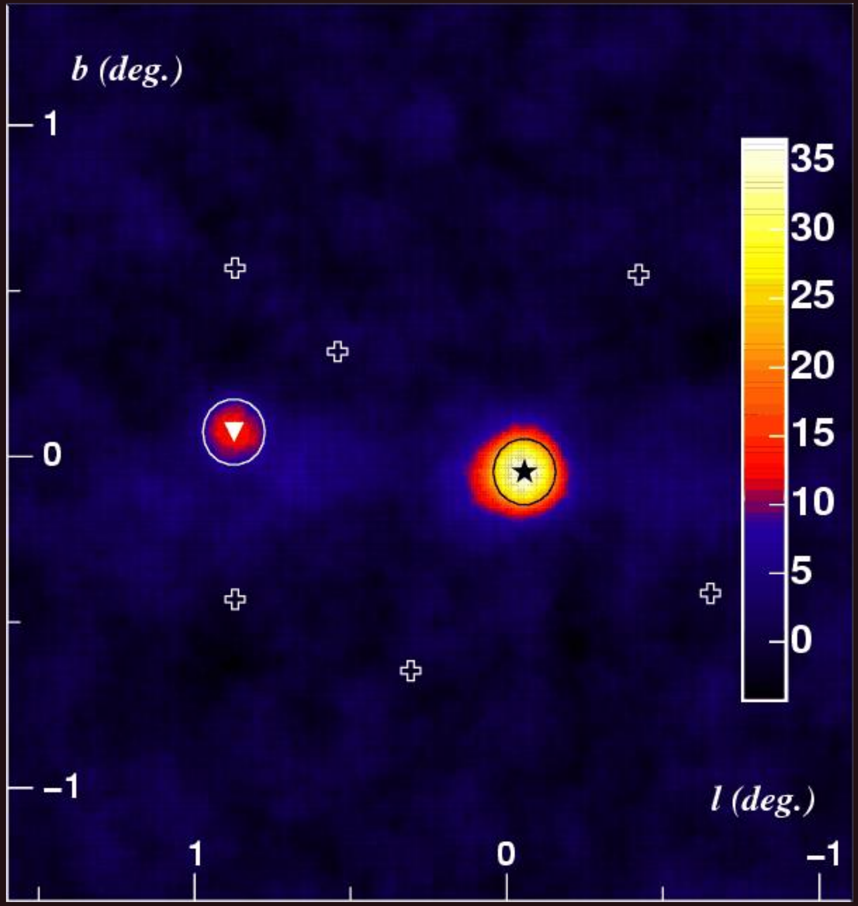
Probably, there have been several strong flares in the past 1307.3954.

More Integral data



1007.4174

Sgr A* and H.E.S.S.



See astro-ph/0503354, 0709.3729

Still, resolution is not good enough to exclude the contribution of some near-by (to Sgr A*) sources.

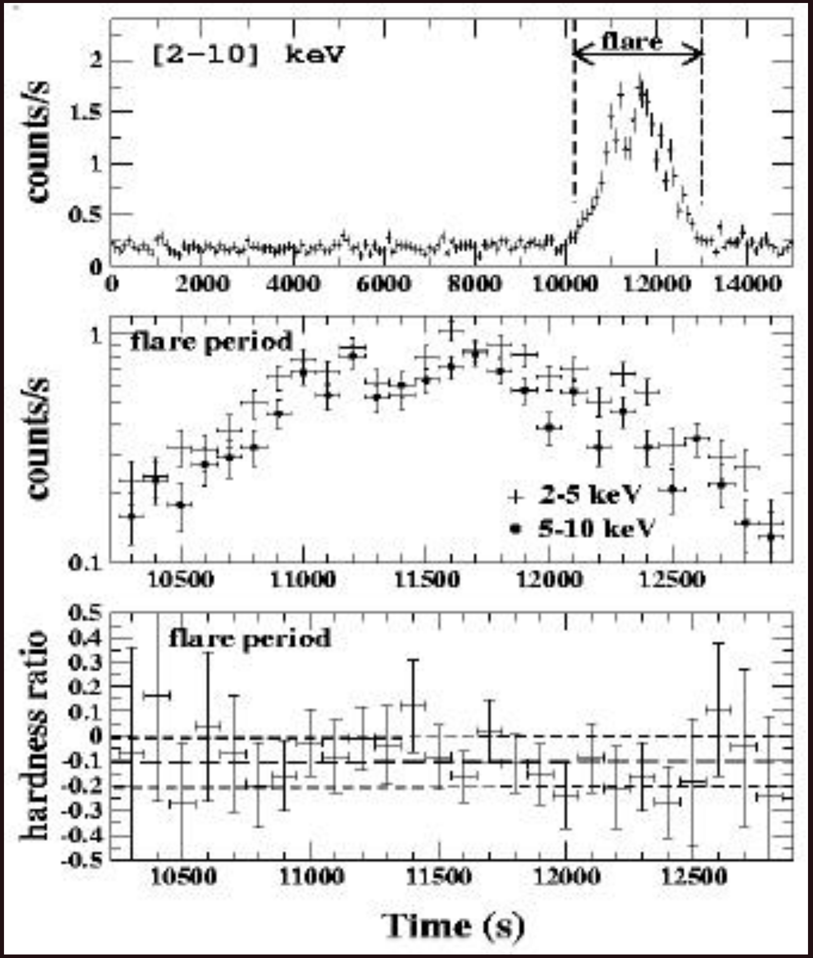
(Aharonian et al. 2005)

X-ray bursts from Sgr A*

Bursts can happen about once in a day.
The flux is increased by a factor of a few (sometimes even stronger).

A bright burst was observed on Oct. 3, 2002 (D. Porquet et al. astro-ph/0307110).
Duration: 2.7 ksec.
The fluxed increased by a factor ~160.
Luminosity: 3.6 10^{35} erg/s.

In one of the bursts, on Aug. 31,2004, QPOs have been discovered.
The characteristic time: 22.2 minutes (astro-ph/0604337).
In the framework of a simple model this means that a=0.22.



SWIFT monitoring of Sgr A*

Active galactic nuclei and quasars

The classification is not very clear

- Quasars
  a) radio quiet (two types are distinguished)
  b) radio loud
  c) OVV (Optically Violently Variable)
- Active galaxies
  a) Seyfert galaxies (types 1 and 2)
  b) radio galaxies
  c) LINERs
  d) BL Lac objects

- Radio quiet
  a) radio quiet quasars, i.e. QSO (types 1 and 2)
  b) Seyfert galaxies
  c) LINERs
- Radio loud
  a) quasars
  b) radio galaxies
  c) blazars (BL Lacs и OVV)

(see, for example, astro-ph/0312545)

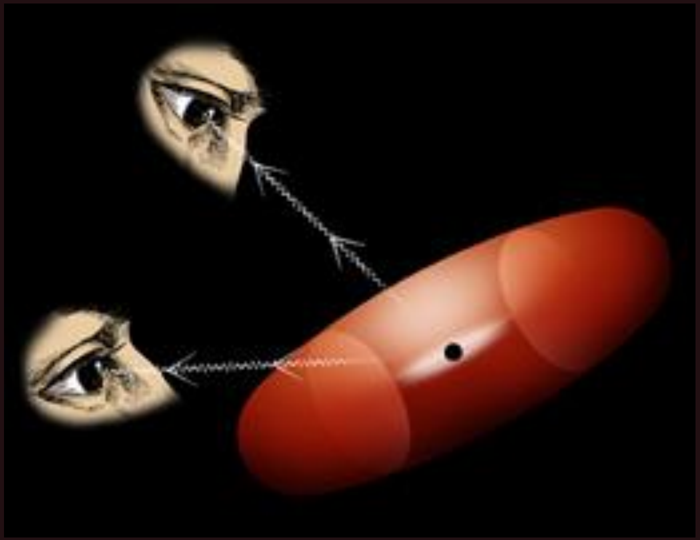
Ballantyne et al. astro-ph/0609002



What should be taken into account

- Relative fracton of nuclei obscured by toruses
- Luminosity distribution of nuclei
- Spectral energy distribution
- Evolution of all these parameters

Mass determination in the case of SMBHs

- Relation between a BH mass and a bulge mass (velocity dispersion).
- Measurements of orbits of stars and masers around a BH.
- Gas kinematics.
- Stellar density profile.
- Reverberation mapping.

Also, always a simple upper limit can be put based on the fact that the total luminosity cannot be higher than the Eddington value.

1001.3675

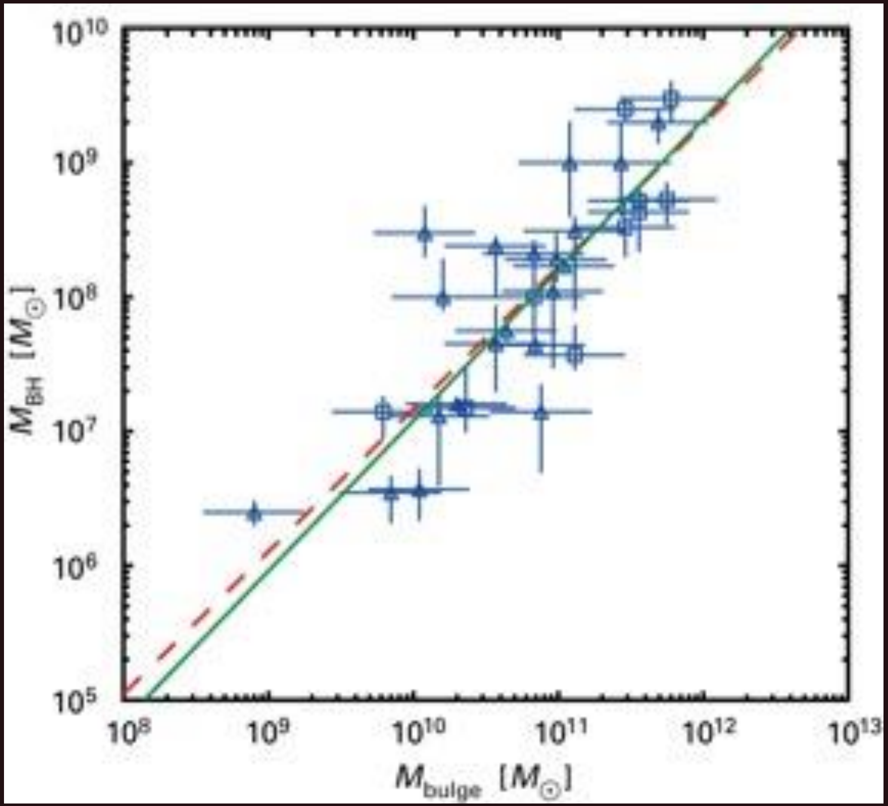
BH mass vs. bulge mass

According to the standard picture every galaxy with a significant bulge has a SMBH in the center.

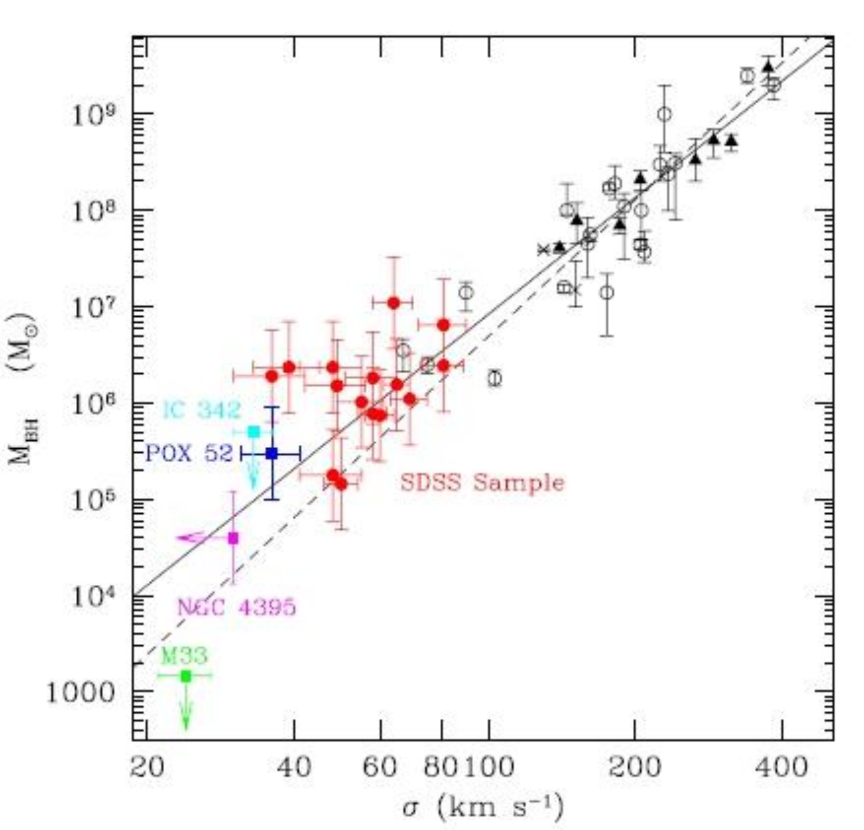


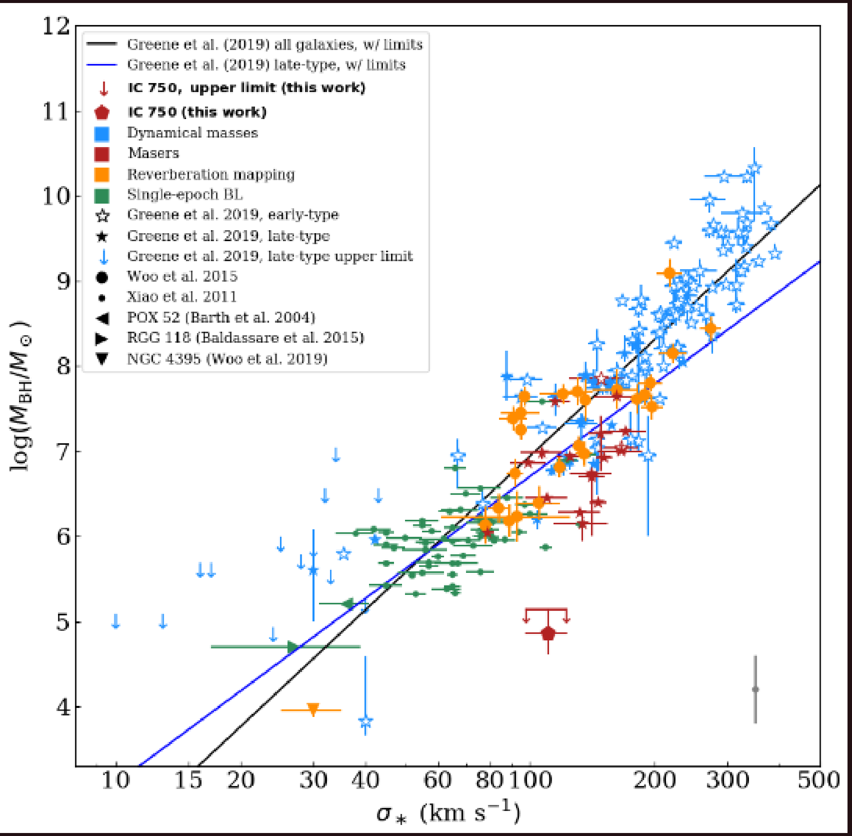
$M_{BH} \sim M_{bulge}^{1.12+/-0.06}$
(Haering, Rix astro-ph/0402376)

BH mass usually is about from 0.1% up to several tenth of percent of the bulge mass.

However, the situation is a little bit more complicated. BH mass correlates differently with different components of a galaxy (see 1304.7762 and 1308.6483).

Exceptions: M33 and others





2006.01114

The upper limit on the BH mass in M33 is an order of magnitude lower than it should be according to the standard relation.

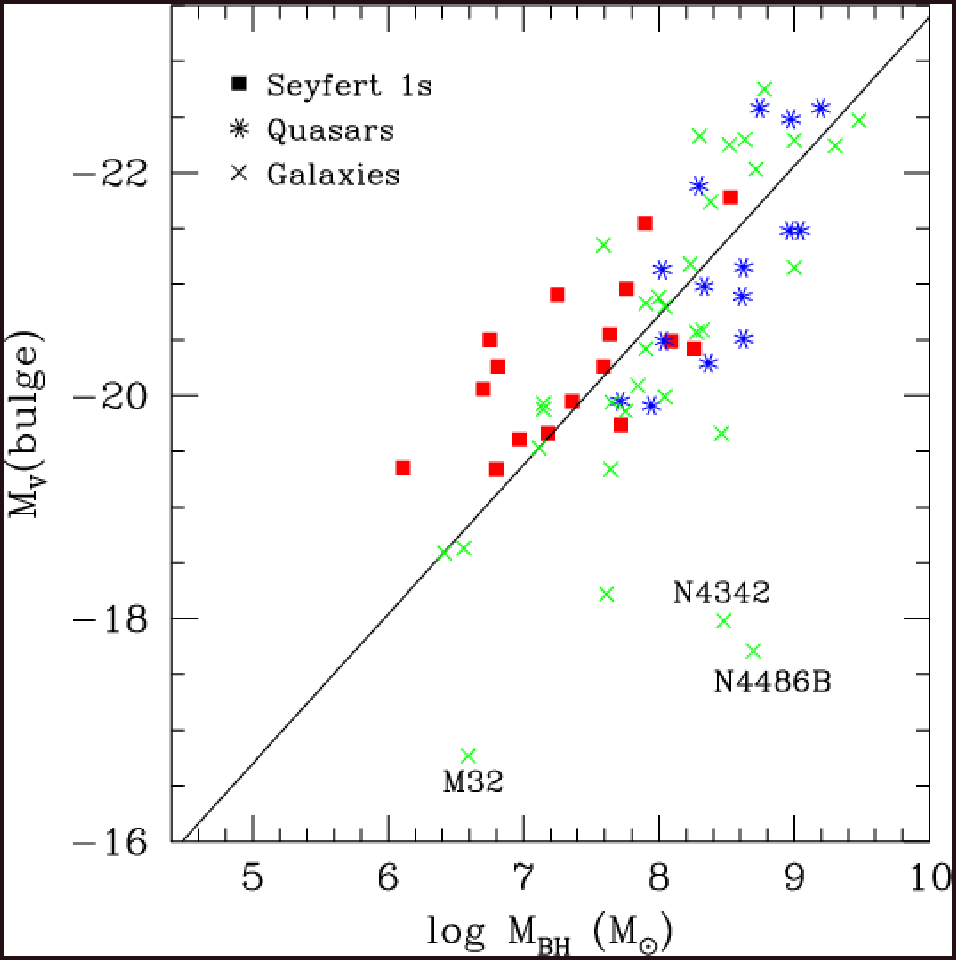
2002.00972

There are other correlations

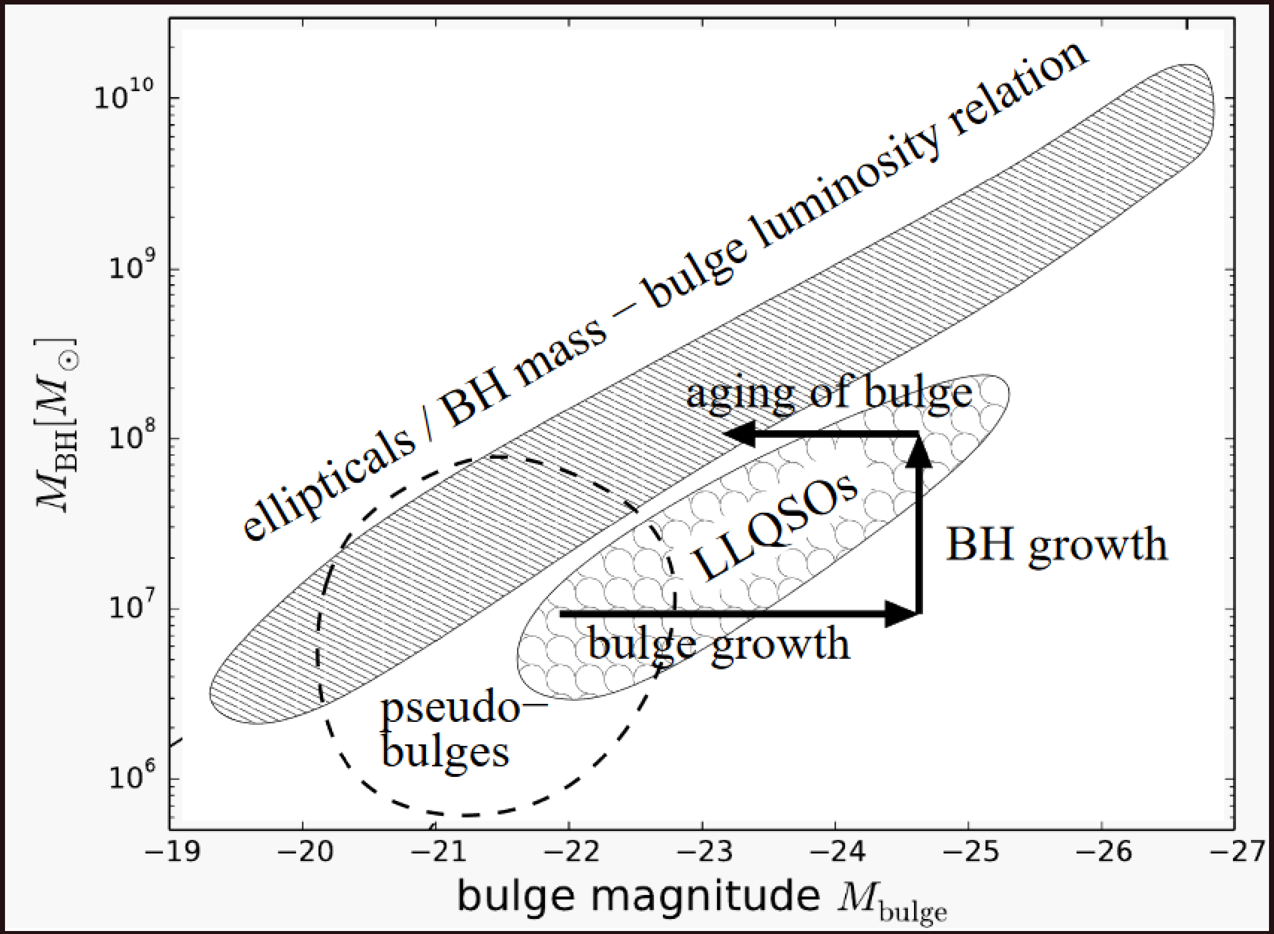


In the figure the following correlation is shown: absolute magnitude of the bulge (in V filter) vs. BH mass.
BH masses are obtained by reverberation mapping.

Other correlations are discussed in the literature.

Wu, Han A&A 380, 31-39, 2001

Origin of black hole mass – bulge magnitude correlation



A possible evolutionary scenario in the BH mass - bulge luminosity diagram. Accretion of matter onto the central region results into enhanced star formation and BH growth. Young stellar populations cause overluminous bulges compared to inactive galaxies on the relation. BH growth and aging of the stellar populations then move the objects back onto the relation.

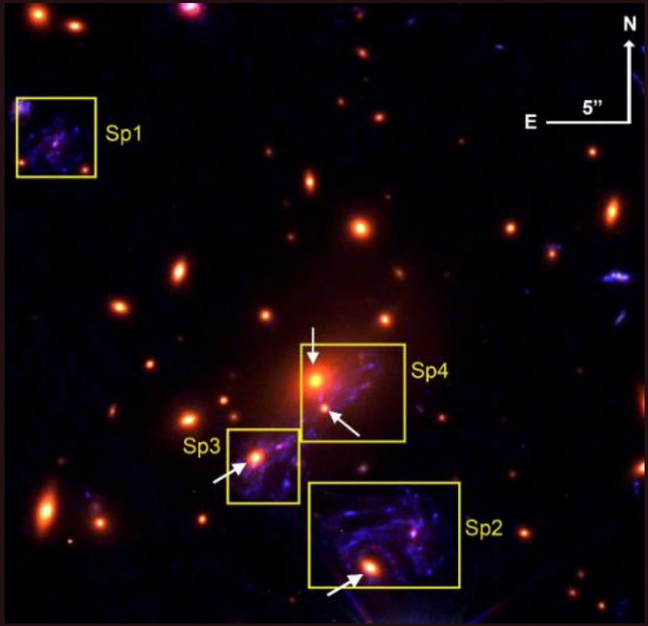
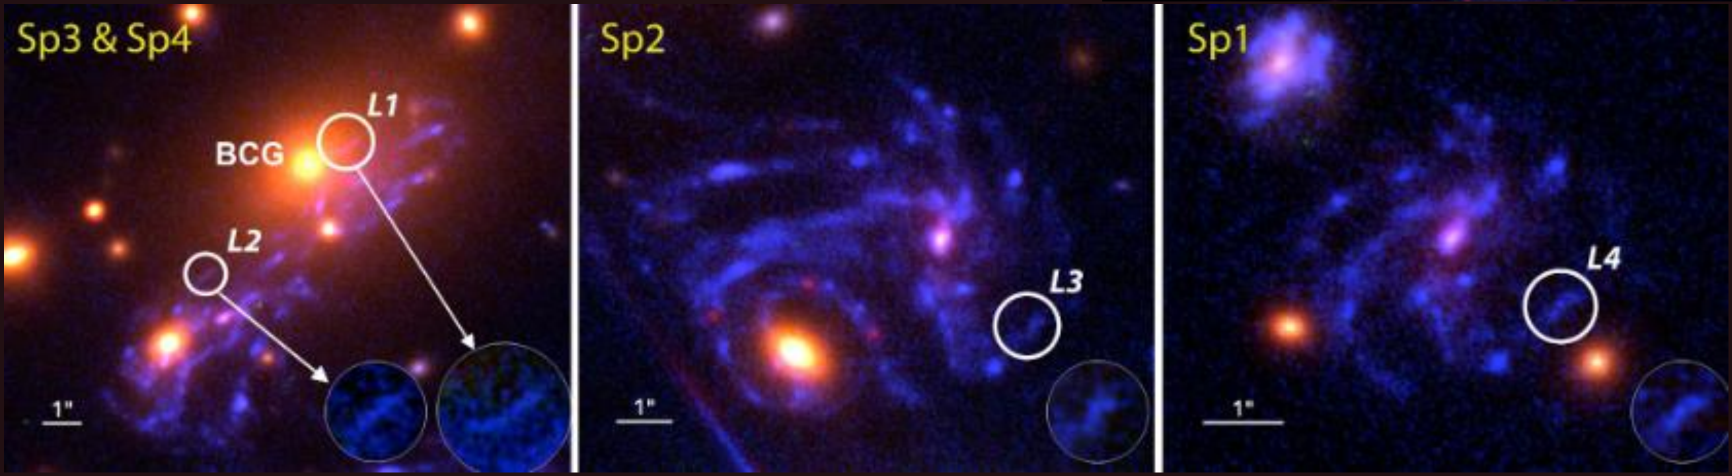
Fits with an off-center SMBHs are the best.
Other explanations (a compact galaxy) are still possible.
SMBH mass estimate is ~7-12 billion solar masses.





1805.05051

Reverberation mapping

The method is based on measuring the response of irradiated gas to changes in the luminosity of a central sources emitting is continuum.
Initially, the method was proposed and used to study novae and SN Ia.
In the field of AGN was used for the first time in 1972 (Bahcall et al.)
An important early paper: Blandford, McKee 1982.

What is measured is the delay between changes in the light curve in continuum and in spectral lines. From this delay the size of BLR is determined.
To apply this method it is necessary to monitor a source.

$$M_{BH} = fG^{-1}R_{BLR}V^2,$$

dimensionless factor,
depending on the geometry of BLR
and kinematics in BLR

clouds velocities in BLR

The method is not good for very bright and very weak AGNs.

(For details see arxiv:0705.1722)

See a detailed recent example in 1104.4794

General scheme

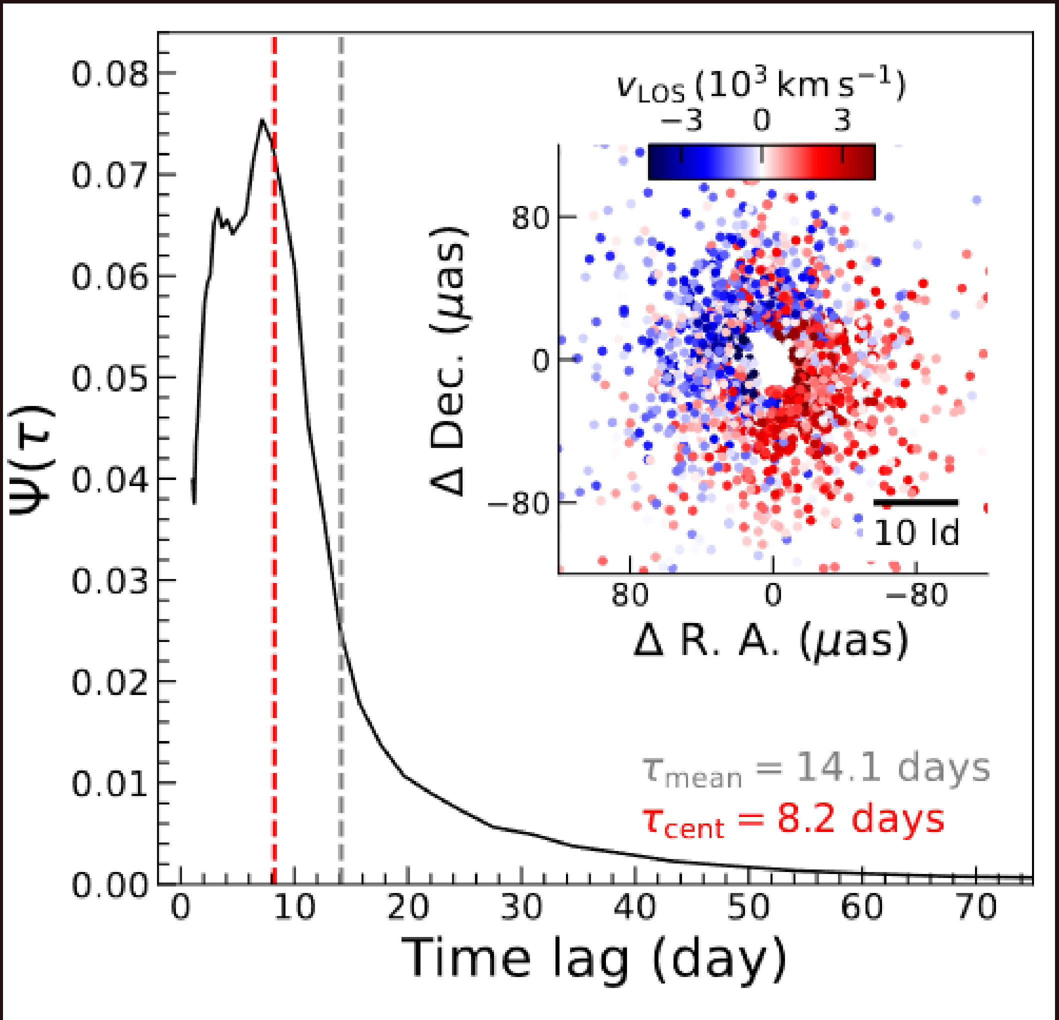
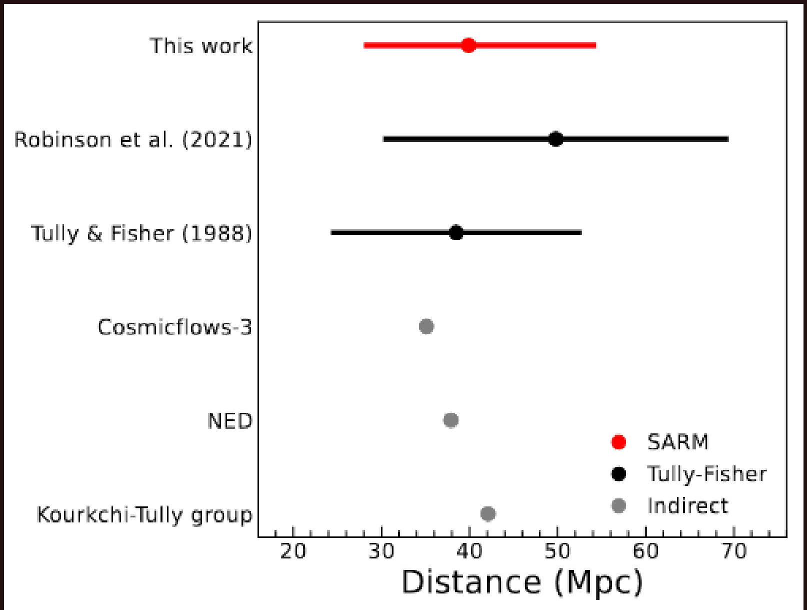
Mass and distance measurement



Distance (Mpc)	Method description
$39.9^{+14.5}_{-11.9}$	SARM (this work)
49.8 ± 19.6	Tully-Fisher relation (Robinson et al. 2021)
38.5 ± 14.2	Tully-Fisher relation (Tully & Fisher 1988)
35.1	Cosmicflows-3 (EDD; Kourkchi et al. 2020)
37.9	NED (Virgo + GA + Shapley)
42.1	Galaxy group (Kourkchi & Tully 2017)



Population synthesis in astrophysics

A population synthesis is a method
of a direct modeling of
relatively large populations of
weakly interacting objects
with non-trivial evolution.
As a rule, the evolution of the objects
is followed from their birth
up to the present moment.

(see astro-ph/0411792)

Two variants

Evolutionary and Empirical

1. <u>Evolutionary PS.</u>
   The evolution is followed from some early stage.
   Typically, an artificial population is formed (especially, in Monte Carlo simulations)
2. <u>Empirical PS.</u>
   It is used, for example, to study integral properties (spectra) of unresolved populations.
   A library of spectra is used to predict integral properties.

Origin of SMBHs

High redshift AGNs

Future observations might reveal many AGNs with moderate luminosities at high z.

This will allow to probe early evolution of SMBHs.
